## Abstract

The Blizzard Challenge 2009 was the fifth annual Blizzard Challenge. As in 2008, UK English and Mandarin Chinese were the chosen languages for the 2009 Challenge. The English corpus was the same one used in 2008. The Mandarin corpus was provided by iFLYTEK. As usual, participants with limited resources or limited experience in these languages had the option of using unaligned labels that were provided for both corpora and for the test sentences. An accent-specific pronunciation dictionary was also available for the English speaker. This year, the tasks were organised in the form of ‘hubs’ and ‘spokes’ where each hub task involved building a general-purpose voice and each spoke task involved building a voice for a specific application.

A set of test sentences was released to participants, who were given a limited time in which to synthesise them and submit the synthetic speech. An online listening test was conducted to evaluate naturalness, intelligibility, degree of similarity to the original speaker and, for one of the spoke tasks, “appropriateness.”

**Index Terms:** Blizzard Challenge, speech synthesis, evaluation, listening test

## 1. Introduction

The Blizzard Challenge, conceived by Black and Tokuda [1], is the international evaluation of corpus-based speech synthesisers open to any participant. Blizzard Challenges are scientific research exercises, not competitions, in which participants use a common corpus to build speech synthesisers. A common test set is then synthesised and a large listening test is used to obtain listeners’ judgements regarding the overall naturalness of the speech, its intelligibility and how similar it sounds to the original speaker. In this, the 2009 Challenge, we used the same general setup as in recent challenges, but with the tasks organised into a hub and spoke structure, as explained in this paper.

The first two Blizzard Challenges, in 2005 and 2006, were organised by Carnegie Mellon University, USA, with the 2007, 2008 and 2009 Challenges being organised by the Centre for Speech Technology Research (CSTR) at the University of Edinburgh, UK. For general details of Blizzard, the rules of participation, a timeline, and information on previous and future Blizzard Challenges, see the website [2].

## 2. Participants

The Blizzard Challenge 2005 [1, 3] had 6 participants, Blizzard 2006 had 14 [4], Blizzard 2007 had 16 [5] and Blizzard 2008 had 19 (18 for English, 11 for Mandarin) [6]. This year, there were again 19 participants, listed in Table 1. One participant requested to withdraw from the Challenge after the listening test was completed. The results for this system (‘ANON’ in Table 1) have been retained in the tables and plots presented here and in the complete set of results distributed to participants. This is important, because listener scores obtained using 5-point scales are effectively internally normalised by listeners with respect to the range of stimuli

they are presented with. In other words, the similarity and naturalness ratings of any individual system are relative to the scores of all the other systems present in the listening test. The upper end of the 5-point scale can be fixed by the inclusion of natural speech, but the remainder of the scale is calibrated only by the other systems present in the test. Proper interpretation of the results therefore requires presentation of the scores from all systems together. In future Blizzard Challenges, we may explicitly disallow withdrawal after distribution of results.

Three systems from previous challenges were used as benchmarks, in an attempt to facilitate comparisons between the results from one year to another: a Festival-based system from CSTR configured very similarly to the Festival/CSTR entry to Blizzard 2006 [7], an HTS speaker-dependent system configured the same as the HTS entry to Blizzard 2005 [8] and the HTS speaker-adaptive system from Blizzard 2007 [9]. Whilst precise calibration of Mean Opinion Score (MOS) ratings across different listening tests (with different participating systems and different listeners) is almost certainly not possible, the *ranking* of a system relative to these benchmarks may possibly be meaningfully compared from one year to another. Comparisons of the absolute scores across different years should be avoided, noting both the point made above about the relative nature of such scores and also that each year different sentences and a different pool of listeners is used.

The tasks completed by each participant are shown in Table 2. As in previous years, a number of additional groups (not listed here) registered for the Challenge and obtained the corpora, but did not submit samples for evaluation. When reporting anonymised results, the systems are identified using letters, with A denoting natural speech, B to D denoting the three benchmark systems and E to W denoting the nineteen systems submitted by participants in the Challenge.

## 3. Voices to be built

### 3.1. Speech databases

The English data for voice building was provided by the Centre for Speech Technology Research, University of Edinburgh, UK. Participants who had signed a user agreement were able to download about 15 hours of recordings of a UK English male speaker with a fairly standard RP accent. An accent-specific pronunciation dictionary, and Festival utterance files created using this dictionary, were also available for the English speaker, under a separate licence. This is exactly the same data used for the 2008 Challenge.

For Mandarin, the ANHUI USTC iFLYTEK Company, Ltd. (iFLYTEK) released a 10 hour / 6000 utterance Mandarin Chinese database of a young female professional radio broadcaster with a standard Beijing accent, reading news sentences. The first 1000 sentences were manually phonetically segmented and prosodically labelled, with the remainder being segmented or labelled automatically. Because it was not possible to make additional recordings of this speaker, no natural semantically unpredictable sentences were available this year. However, we took the

view that this was a reasonable price to pay, given the opportunity to use a commercially-produced corpus.

### 3.2. Tasks

Participants were asked to build several synthetic voices from the databases, in accordance with the rules of the challenge [10]. A hub and spoke design was adopted this year. Hub tasks contain ‘H’ in the task name, spoke tasks contain ‘S’ and each are described in the following sections.

#### 3.2.1. English tasks

- EH1: English full voice from the full dataset (about 15 hours)
- EH2: English ARCTIC voice from the ARCTIC [11] subset (about 1 hour)
- ES1: build voices from the specified ‘E\_SMALL10’, ‘E\_SMALL50’ and ‘E\_SMALL100’ datasets, which con-

System short name	Details
NATURAL	Natural speech from the same speaker as the corpus
FESTIVAL	The Festival unit-selection benchmark system [7]
HTS2005	A speaker-dependent HMM-based benchmark system [8]
HTS2007	A speaker-adaptive HMM-based benchmark system [9]
AHOLAB	Aholab, University of the Basque Country, Spain
ANON	Identity withheld
CASIA	National Laboratory of Pattern Recognition, Institute of Automation, Chinese Academy of Sciences, China
CEREPROC	CereProc Ltd, UK
CMU	Carnegie Mellon University, USA
CSTR	The Centre for Speech Technology Research, University of Edinburgh, UK
DFKI	DFKI GmbH, Germany
EMIME	The EMIME project consortium
I2R	Institute for Infocomm Research (I <sup>2</sup> R), Singapore
ITRI	Industrial Technology Research Institute, Taiwan
IVO	IVO Software Sp. z o. o.
MXAC	$\mu$ Xac, Australia
NICT	National Institute of Information and Communications Technology, Japan
NIT	Nagoya Institute of Technology, Japan
NTUT	National Taipei University of Technology, Taiwan
SHRC	Speech and Hearing Research Center, Peking University, China
TOSHIBA	Research and Development Center, Toshiba (China)
USTC	iFlytek Speech Lab, University of Science and Technology of China
VUB	Vrije Universiteit, Belgium

Table 1: The participating systems and their short names. The first four rows are the benchmark systems and correspond to the system identifiers A to D in that order. The remaining rows are in alphabetical order of the system’s short name and *not* the order E to W.

System	EH1	EH2	ES1	ES2	ES3	MH	MS1	MS2
NATURAL	X	X	X	X	X	X	X	X
FESTIVAL	X	X		X

Table 2: The tasks completed by each participating system. The first four rows are the benchmark systems and correspond to the system identifiers A to D in that order. The remaining rows are in alphabetical order of the system’s short name and *not* the order E to W

sist of the first 10, 50 and 100 sentences respectively of the ‘ARCTIC’ subset. Participants could use voice conversion, speaker adaptation techniques or any other technique.

- ES2: build a voice from the full UK English database suitable for synthesising speech to be transmitted via a telephone channel. The telephone channel simulation tool described in Section 3.3 was made available to assist participants in system development. It was permissible to enter the same voice as task EH1 or EH2, but specially-designed voices were strongly encouraged.
- ES3: build a voice from the full UK English database suitable for synthesising the computer role in a human-computer dialogue. A set of development dialogues were provided, from the same domain as the test dialogues. Participants could enter the same voice as task EH1 or EH2, but again specially-designed voices were strongly encouraged. Participants were allowed to add simple markup to the text, either automatically or manually, if they wished. The markup had to be of a type that could conceivably be provided by a text-generation system (e.g. emphasis tags were acceptable, but a handcrafted F0 contour was not).

#### 3.2.2. Mandarin tasks

- MH: Mandarin voice from the full dataset (about 10 hours / 6000 utterances / 130000 Chinese characters)
- MS1: build voices from each of the specified ‘M\_SMALL10’, ‘M\_SMALL50’ and ‘M\_SMALL100’ datasets, which consist of the first 10, 50 and 100 sentences respectively of the full Mandarin database. Same rules as ES1.
- MS2: build a voice from the full Mandarin database suitable for synthesising speech to be transmitted via a telephone channel. Same rules as ES2.

Figure 1: The pipeline of processes used to simulate the telephone channel. Input and output are headerless PCM files at 8kHz sampling rate and 16 bit sample depth.

### 3.3. Telephone channel simulation for tasks ES2 and MS2

In order to investigate the effects of telephone channels on the intelligibility of the submitted synthetic speech, a simulated telephone channel was used. Although it would have added more realism to present listeners with the stimuli monaurally using a telephone handset, this was not practical for the large numbers of listeners required by the Blizzard Challenge.

The simulated channel was implemented using the “G.191: Software tools for speech and audio coding standardization” software freely available from the ITU<sup>1</sup> with a pipeline of processes kindly suggested by Telekom Laboratories & The Quality and Usability Lab at TU Berlin, shown in Figure 1. We elected to implement a relatively low quality channel with a 16kbps transmission rate.

Participants were provided with this pipeline, should they wish to use it during development of their ES2 and MS2 voices. They were encouraged to build special voices for these tasks, but were allowed to enter their EH1, EH2 or MH1 voices instead.

### 3.4. Appropriateness (task ES3)

At previous Blizzard workshops there was a clear desire to evaluate more than just naturalness and intelligibility; specifically, participants wished to evaluate synthetic speech in a particular usage context. Therefore, we conceived task ES3 in which the synthetic speech was evaluated in a simulated human-computer dialogue. A real-time dialogue system, which dynamically generates the computer response, would require participants to submit run-time synthesisers. It was decided that this would be unattractive for some participants, and impractical for the organisers. Therefore, we used pairs of dialogue utterances comprising one user’s query to the system followed by the system’s response. These were kindly provided by the CLASSIC project<sup>2</sup> and were in a restaurant recommendation domain. The sentences were manually adjusted by the Blizzard organisers in order to remove difficult-to-pronounce

restaurant names (e.g. French words). Since these dialogue pairs were static, participants could pre-synthesise all the system utterances and submit them for evaluation. For the test sentences, the texts of both the user query and the corresponding system response were provided to participants.

## 4. Listening test design

### 4.1. Interface

The listening evaluation was conducted online, using the design developed for Blizzard 2007 [5] and refined in Blizzard 2008 [6], which was itself developed from designs in previous challenges [1, 3, 4]. The registration page for each listener type presented an overview of the listening test and the tasks to be completed. It was possible for a listener to register for both the English and Mandarin listening tests separately, if they wished. Please refer to [5] for a complete description of the listening test interface.

### 4.2. Materials

The participants were asked to synthesise several hundred test sentences (including the complete Blizzard Challenge 2007 and 2008 test sets, to be retained as a resource for future experimentation), of which a subset were used in the listening test. The selection of which sentences to use in the listening tests was made as in 2008 – please see [6] for details. Permission has been obtained from almost all participants to distribute parts of this dataset along with the listener scores; we hope to find the resources to do this shortly. For English, participants synthesised sentences that had been held out from the corpus (so that natural speech samples were available for them) plus Semantically Unpredictable Sentences (SUS) [12] generated using a tool provided by Tim Bunnell of the University of Delaware and recorded by us specially for the Challenge with the same speaker as the distributed corpus. These SUS conform more closely to the original specification [12] and use simpler words than the SUS used in previous Blizzard Challenges. In order to mitigate this and avoid ceiling effects, listeners were only permitted to play each such sentence once. For Mandarin, held out sentences were also used. The SUS for Mandarin were generated using the same tool as in 2008. Natural SUS were not available for Mandarin, since the original speaker was not available.

### 4.3. Listener types

Various listener types were employed in the test: letters in parenthesis below are the identifiers used for each type in the results distributed to participants. For English, the following listener types were used:

- Volunteers recruited via participants, mailing lists, blogs, etc. (ER).
- Speech experts, recruited via participants and mailing lists (ES).
- Paid UK undergraduates, native speakers of UK English, aged about 18-25. These were recruited in Edinburgh and carried out the test in purpose-built soundproof listening booths using good quality audio interfaces and headphones (EU).

For Mandarin, the following listener types were used:

- Paid native speakers of Mandarin, aged 18-25, recruited in China using a commercial testing organisation, who carried out the test in a quiet supervised lab using headphones (MC).
- Paid undergraduate native speakers of Mandarin aged about 20-25. These were recruited in Edinburgh and carried out the test in purpose-built soundproof listening booths using good quality audio interfaces and headphones (ME).

10	ES2	SUS

Table 3: The three listening tests conducted for English.

- Volunteers, recruited via participants, mailing lists, etc. (MR).
- Speech Experts, recruited via participants and mailing lists (MS).

Tables 29 to 35, summarised in Table 5, show the number of listeners of each type obtained for each of the listening tests listed in Tables 3 and 4.

#### 4.4. Listening tests

Since the tests for tasks ES1, ES2, MS1 and MS2 were relatively short, they were combined into pairs in order to make the best use of available listeners. Only two participants entered ES3 voices, so the listening test for this task was handled differently. Rather than simply performing a comparison between these two systems, they were included in two sections of the main EH1 and EH2 listening tests, as described in Section 4.4.1. Tables 3 and 4 show the five independent listening tests that were run in parallel for this year’s Blizzard Challenge. Each listener performed one of the three English tests or one of the two Mandarin tests (or, possibly one English test *and* one Mandarin test). Each test followed the same general design, although the number and type of sections varied, as described in the tables. Within each numbered section of a listening test, the listener generally heard one example from each system, with the exception of the MDS sections (which involved pairwise comparisons) and the MOSconv/MOSapp sections in tests EH1+ES3 and EH2+ES3. Note that the number of systems involved in each task varies; where there were more systems, and therefore larger Latin Squares, fewer sections could be included in the corresponding listening test. Samples of the original speaker were included in all sections, except for Mandarin SUS.

Section number	Tasks being evaluated	Type (see Section 4.4.1)

12	MS2	SUS

Table 4: The two listening tests conducted for Mandarin.

##### 4.4.1. Description of each type of section in the listening test

**SIM** In each part listeners could play 4 reference samples of the original speaker and one synthetic sample. They chose a response that represented how similar the synthetic voice sounded to the voice in the reference samples on a scale from 1 [Sounds like a totally different person] to 5 [Sounds like exactly the same person].

**MDS** In each part listeners heard one sample from each of two of the participating systems, (or, in the case of one system ordering for each dataset, two samples from the same system). Listeners were asked to ignore the meanings of the sentences and instead concentrate on how natural or unnatural each one sounded. They then chose whether in their opinion the two sentences were similar or different in terms of their overall naturalness. The results of this section are intended for analysis using Multidimensional Scaling (not presented here).

**MOSnews** Mean Opinion Score (MOS - naturalness), news domain. In each part listeners listened to one sample and chose a score which represented how natural or unnatural the sentence sounded on a scale of 1 [Completely Unnatural] to 5 [Completely Natural].

**MOSconv** Mean Opinion Score (MOS - naturalness), conversational domain. In each part listeners listened to one sample and chose a score which represented how natural or unnatural the sentence sounded on a scale of 1 [Completely Unnatural] to 5 [Completely Natural].

There were only two entries to the ES3 task, so we devised a listening test design in which the listening tests EH1+ES3 and EH2+ES3 included sections in which samples from the two ES3 systems that were submitted, plus samples from all systems for voice EH1 or EH2. However, due to a small error in the listening test scripts, these two sections actually contained samples from all EH1 systems *except* the EH1 samples from the two teams that submitted an ES3 voice, but *including* samples from the ES3 voice of those two teams. The consequence of this is that the EH1 samples from those two teams were evaluated by fewer listeners than intended. We used the results for all EH1 samples from both MOSconv sections (the ones from test EH1+ES3, and the one from test EH2+ES3) to compute the MOS scores for voice

EH1. The results from the ES3 samples are presented separately.

**SUS** Semantically Unpredictable Sentences (SUS) designed to test the intelligibility of the synthetic speech. Listeners heard one utterance in each part and typed in what they heard. The error rates were computed as in previous years [5, 6].

**MOSapp** Mean opinion scores (MOS - appropriateness), conversational domain. In each part, listeners saw a question (provided in text form only) of the type that a human user might ask a restaurant enquiry service, and then listened to one spoken sample that represented the response to that question. Listeners chose a score which represented how appropriate or not the response sounded in that dialogue context on a scale of 1 [Completely Inappropriate] to 5 [Completely Appropriate]. For this section we used the samples from the two teams that submitted a separate voice for ES3; we decided to also add EH1 samples from all the other teams. The results are presented together.

#### 4.4.2. Number of listeners

The listener responses used for the distributed results were extracted from the database on 26th June 2009 after the online evaluation had been running for approximately six weeks. The number of listeners obtained is shown in Table 5.

	English	Mandarin
Total registered	482	334
<i>of which:</i>		
Completed all sections	365	311
Partially completed	59	14
No response at all	58	9

Table 5: Number of listeners obtained

See Table 28 for a detailed breakdown of evaluation completion rates for each listener type. As in last year’s challenge, the higher completion rate for Mandarin listeners is a consequence of the higher proportion of paid listeners.

## 5. Analysis methodology

As in previous years, we pooled ‘completed all sections’ and ‘partially completed’ listeners together in all analyses. Here, we present only results for all listener types combined. Analysis by listener type was provided to participants. Please refer to [13] for a complete description of the statistical analysis techniques used and justification of the statistical significance techniques employed. As usual, system names are anonymised in all distributed results. See Section 7.3 and Tables 23 to 63 for a summary of the responses to the questionnaire that listeners were asked to optionally complete at the end of the listening test.

## 6. Results

Standard boxplots are presented for the ordinal data where the median is represented by a solid bar across a box showing the quartiles; whiskers extend to 1.5 times the inter-quartile range and outliers beyond this are represented as circles. Bar charts are presented for the word error rate type interval data. A single ordering of the systems is employed in all plots for a particular language. This ordering is in descending order of the mean MOS (combining MOSnews and MOSconv) for the main task (EH1 or MH) – see Tables 6 and 8. Note that this ordering is intended only to make the plots more readable and *cannot be interpreted as a ranking*. In other words, the ordering does not tell us anything about which systems are significantly better than other systems.

System	median	MAD	mean	sd	n	na
A	5	0.0	4.9	0.38	463	43
B	3	1.5	2.9	1.06	457	49
C	3	1.5	2.7	1.07	463	43
D	2	1.5	2.5	1.02	456	50
E	2	1.5	2.1	1.01	462	44
H	3	1.5	2.8	1.01	463	43
I	3	1.5	3.1	1.02	462	44
J	2	1.5	2.4	0.98	463	43
K	4	1.5	3.8	0.88	457	49
L	3	1.5	2.8	0.97	457	49
M	2	1.5	1.9	0.92	462	44
O	3	1.5	2.6	0.98	463	43
P	2	1.5	2.0	0.98	457	49
Q	2	1.5	2.1	0.93	463	43
R	2	1.5	2.1	0.97	463	43
S	4	1.5	4.2	0.71	163	343
T	2	1.5	2.0	0.97	463	43
W	2	1.5	2.1	0.94	456	50

Table 6: Mean opinion scores for task EH1 (full data set) on the combined results from sections 3 and 4 of the EH1+ES3 listening test, excluding the ES3 samples. Table shows median, median absolute deviation (MAD), mean, standard deviation (sd), n and na (data points excluded). Note the high value of na for system S – this is due to the error in the setup of section 4 of this listening test.

### 6.1. Task EH1

Table 6 presents descriptive statistics for the mean opinion scores for English task EH1. Figure 2 displays the results of the tests graphically. As expected, we see that natural speech (system A) has a MOS naturalness of 5. Inspecting the Bonferoni-corrected pairwise Wilcoxon signed rank significance tests ( $\alpha = 0.01$ ) for naturalness presented in Table 11 reveals that system A is significantly different from all other systems. We can therefore say that no synthesiser is as natural as the natural speech. Systems S and K, whilst not as natural as the natural speech, are both significantly more natural than all other systems.

From the plot of similarity scores and by referring to Table 10, we can also say that, although systems K and S are significantly less similar to the original speaker than natural speech, they are both significantly more similar to the original speaker than all other systems, for English task EH1. Likewise, from Table 11, systems S and K are equally natural and significantly more natural than all other systems, although significantly less natural than natural speech.

System S is as intelligible as natural speech (Table 12). However, there is no significant difference between system S and a number of other systems (B,C,K,L,O,P), so we cannot state that system S is more intelligible than other systems.

### 6.2. Task EH2

For English task EH2, results are given in Table 7 and Figure 3 with statistical significances shown in Table 13 for similarity, Table 14 for naturalness and Table 15 for intelligibility. Again, no system is as natural as the natural speech, or as similar to the original speaker. There is no system that is clearly more natural than the rest. Although it was as intelligible as natural speech on task EH1, system S is no longer as intelligible as natural speech on task EH2.

### 6.3. Task ES1

In both English and Mandarin, we chose to evaluate just one of the three voices built for this task. For task ES1, we selected the

System	median	MAD	mean	sd	n	na
A	5	0.0	4.8	0.47	139	13
B	3	1.5	2.9	1.08	140	12
C	3	1.5	3.2	0.94	140	12
D	3	1.5	2.6	0.97	141	11
E	2	1.5	1.7	0.83	140	12
H	3	1.5	2.6	0.94	140	12
I	3	1.5	3.3	0.98	141	11
J	3	1.5	2.6	1.03	140	12
K	4	0.0	3.6	0.89	140	12
L	3	1.5	3.3	1.01	139	13
M	2	1.5	1.8	0.89	140	12
O	2	1.5	2.5	0.92	141	11
P	2	1.5	2.4	0.99	141	11
Q	3	1.5	2.5	1.03	140	12
R	2	1.5	2.3	0.88	140	12
S	4	1.5	3.7	0.92	141	11
T	2	1.5	2.2	1.01	140	12
U	2	1.5	1.7	0.88	141	11
W	2	1.5	2.3	0.99	140	12

Table 7: Mean opinion scores for task EH2 (ARCTIC data set) on the combined results from sections 3 and 4 of the EH2+ES3 listening test, excluding the ES3 samples. Table shows median, median absolute deviation (MAD), mean, standard deviation (sd), n and na (data points excluded).

E\_SMALL100 voice, based on preferences expressed by participants who submitted entries for task ES1. For English task ES1 (building a voice from very small amounts of speech), results are given in Figure 4 and significance tests are shown in Table 16.

All systems are rated as unnatural and not similar to the original speaker. Systems J and P are significantly less similar to the original speaker than the other systems. Systems W and D are somewhat more natural than other systems, although this is not significant in all cases.

The systems fall neatly into three groups for intelligibility: natural speech is significantly more intelligible than all synthesisers, systems P, S, D, W and L are equally intelligible, followed by systems H and J.

#### 6.4. Task ES2

For English task ES2 (building a voice for use over the telephone), results are given in Figure 5. Significance tests are shown for naturalness and intelligibility in Table 17. Now there is no system that is as intelligible as natural speech – it appears that synthetic speech may be generally more degraded by the telephone channel than natural speech in terms of intelligibility.

#### 6.5. Task ES3

For English task ES3 (building a voice for a dialogue system), results are given in Figure 6. System S is rated as significantly more appropriate than system U (using the same type of pairwise Wilcoxon signed rank tests as in other tasks), although this may be simply because system U is significantly less natural than system S.

#### 6.6. Task MH

Table 8 and Figure 7 presents the results for the Mandarin hub task MH. The significance tests illustrated in Table 19 show that again, as for English, no system is as natural as the natural speech. The most natural synthesiser is system L which, although less natural than natural speech, is significantly more natural than all other systems.

Since natural SUS were not available for Mandarin this year,

we are unable to test whether any system was as intelligible as natural speech. We can say, from the significance tests illustrated in Table 20, that systems L, F and C are equally intelligible, although only system L is significantly more intelligible than the remaining systems.

With regards to similarity to the original speaker, Table 18 shows that no system was regarded as being as similar to the original speaker as the natural speech. Systems L, F, C and R form a group of systems that appear to be most similar to the original speaker, although only systems L and F are significantly more similar than the remaining systems. Note that system F is actually significantly different to system R within this approximate grouping.

System	median	MAD	mean	sd	n	na
A	5	0.0	4.6	0.79	370	26
C	4	1.5	3.6	0.96	370	26
D	3	1.5	2.9	1.06	370	26
F	4	1.5	3.8	1.07	370	26
G	3	1.5	2.8	1.13	371	25
I	3	1.5	3.3	1.24	370	26
L	4	1.5	4.1	0.93	370	26
M	3	1.5	3.1	1.14	370	26
N	3	1.5	2.8	1.25	370	26
R	4	1.5	3.5	1.04	371	25
V	3	1.5	3.0	1.18	370	26
W	3	1.5	3.1	1.04	370	26

Table 8: Mean opinion scores for task MH. Table shows median, median absolute deviation (MAD), mean, standard deviation (sd), n and na (data points excluded due to missing data)

#### 6.7. Task MS1

For Mandarin task MS1 (building a voice from very small amounts of speech), results are given in Figure 8 and significance tests are shown in Table 21. We selected the M\_SMALL100 voice for evaluation, based on preferences expressed by participants who submitted entries for this task. No system was found to be as natural or as similar to the original speaker as the natural speech. Systems L, R, W and D form a group of systems which sound most similar to the original speaker (although there is a significant difference between system R and system D). System L is significantly more natural than all other systems except W. There are few significant differences in intelligibility between most systems, in terms of PTER.

#### 6.8. Task MS2

For Mandarin task MS2 (building a voice for use over the telephone), results are given in Figure 9. Significance tests are shown for naturalness and intelligibility in Table 22. The natural speech (system A) is no longer rated by listeners as being very similar to the original speaker, although it is still found to be highly natural and significantly more so than any other system. System L is significantly more natural than all other systems, except natural speech. There are relatively few significant differences in intelligibility, with systems C, F, L, V and W forming a group of roughly equally intelligible systems (although there are some significant differences between systems within this group, and also some insignificant differences between some members of this group and the remaining systems).

## 7. Discussion

There is continued interest in the Blizzard Challenge, with 19 teams participating this year. We therefore propose to organise another Challenge in 2010. In 2009, we made several additions

System	Year					
	2007		2008		2009	
	MOS	WER	MOS	WER	MOS	WER
Natural	4.7	–	4.8	22	4.9	14
Festival	3.0	25	3.3	35	2.9	25
HTS 2005	–	–	2.9	33	2.7	23

Table 9: Comparing the results of the benchmark systems for English (main voice, large database) across three years of the Blizzard Challenge. MOS means mean naturalness score and WER means word error rate in percent using semantically unpredictable sentences (SUS). Note that the SUS in 2009 were simpler than those in 2007 and 2008

to the challenge, with varying degrees of success. Both the ‘very small amounts of data’ and ‘speech for transmission by telephone’ tasks seemed popular with participants. The dialogue speech task was not popular, with only two entries, even though from our discussions with past participants this type of application for TTS is widely thought to be important and interesting. Entries to this task probably required considerably more effort, and perhaps needed more expert knowledge of the language (English). We would welcome suggestions for ways to evaluate ‘appropriateness’ or any other measure of how good synthetic speech is in particular usage situations or applications. Task-based scenarios are attractive, since they allow objective measures of task success (e.g. completion rate or time taken). However, they also tend to be lengthy and may require on-line generation of synthetic speech; neither of these are practical for the Blizzard Challenge.

### 7.1. Benchmark systems

The inclusion of the benchmark systems is intended to provide reference points for comparison between different years of the Challenge. If this is to be possible, then the relative ranking of the benchmark systems should be constant from year to year. Table 9 presents the key results for the English benchmark systems for 2007, 2008 and 2009. These results do seem to be consistent year-on-year. WER decreases uniformly by about one third for all systems from 2008 to 2009, due to the simpler SUS used this year. The relative MOS and WER of the three systems is consistent: for MOS, the ranking is Natural–Festival–HTS 2005; for WER, the ranking is Natural–HTS 2005–Festival.

### 7.2. Limitations of the listening test design

The current listening test design has many advantages, including the ability to perform evaluations for quite large number of systems (perhaps up to 25) with a fully balanced design which controls for possible effects of sentence and order of presentation by using a Latin Square design.

We consider this year’s hub and spoke design a success, because it allowed participants to enter whichever tasks they desired. The disappointing number of entries to task ES3 necessitated special treatment in the listening test, which created considerable additional complexity in the design which in turn lead to a small error being made in this part of the test.

However, there are two significant weaknesses which should be considered when designing future listening tests for the Blizzard Challenge:

- The listening tests for each hub and spoke task are conducted independently, making cross-task comparisons impossible. In particular, this year’s test does not allow direct calculation of the difference in intelligibility for a single system between a hub task and the telephone channel spoke task.
- Each new task added increases the number of listeners re-

quired. This year, we were able to use the same listener pool for some pairs of tasks, but this necessitated the use of different sentences in each test (particularly important for SUS) which only increases the difficulty in comparing results across tasks for a single system.

### 7.3. Listener feedback

On completing the evaluation, listeners were given the opportunity to tell us what they thought through an online feedback form. This was the same as in Blizzard 2007 and 2008. All responses were optional. Feedback forms were submitted by all the listeners who completed the evaluation and included many detailed comments and suggestions from all listener types. Listener information and feedback is summarised in Tables 23 to 63.

## 8. Acknowledgements

Rob Clark designed and implemented the statistical analysis; Dong Wang wrote the WER and CER/PTER/PER programmes; Volker Strom and Junichi Yamagishi provided the benchmark systems. Roger Burroughes is ‘roger’, the English voice; Tim Bunnell of the University of Delaware generated the 2009 SUS sentences; iFLYTEK provided the Mandarin data; the listening test scripts are based on earlier versions provided by previous organisers of the Blizzard Challenge. Thanks to all participants and listeners.
